ARCHITECTURE REFERENCE / 21 OCTOBER 2026

/chat workflows
Three highlighted scenarios

Complete flowcharts with applied tools, memory context and expected outcomes.

How to read this document

Each scenario has a one-page explanation followed by the **complete original workflow**. The diagrams are rendered directly from the same three Mermaid sources shared in chat. All nodes, labels, branches and scenario highlights are retained. Diagram pages use an oversized vector canvas. Zoom in to read the labels.

Scenarios and page guide

PROMPT	APPLIED BUSINESS TOOLS	PAGES
01 - Revive-order guidance How revive orders should be processed.	None; explain retrieved procedure.	2-3
02 - USA customers Fetch all customers from USA.	get_customers Apply the illustrative active-only rule.	4-5
03 - Customers and orders Fetch customers and their order details; apply appropriate rules.	get_customers, then get_orders (orders tool is proposed).	6-7

Highlight legend

Yellow - boxes used by the prompt	**Orange** - actual business tool execution
Green - Start / Resume	**Red** - Interrupt / End

Other boxes stay visible for context. A highlighted memory search does not mean every memory type has a match. Initial, result and decline agent boxes are views of the same logical agentModel, called when needed.

Memory scope and shared services

Semantic: organizationId + sessionId. A new session excludes old Semantic context; it does not require physical deletion. **Procedural and Episodic:** organizationId. **threadId:** identifies checkpoint/resume state. **employeeId / userId:** request metadata; business data remains organization-scoped.

Every scenario uses the /chat API, graph state, PostgreSQL memory search and the checkpointer. recordEpisode summarizes and saves the outcome. These internal storage operations are separate from business tools.

Design status

These charts describe the agreed target design. The inspected branch currently has get_customers, create_customer and server_time. It still needs session scope, the merged prompt/intent call, batch Semantic review, an active/status customer filter, and an orders tool. The current eight-planning-turn cap can also limit large paginated fetches.

Memory examples below are illustrative, not confirmed stored records. None of these three prompts requests a business write; the write-review, Semantic-save and resume branches remain visible but inactive.
